

## PREFACE

This report presents population projections for the state of Rhode Island and its 39 cities and towns from 1970 to 2040 by five year intervals. State projections are shown by five year age, sex, and white and non-white designation, while city and town forecasts are presented by totals only. State total fluctuations are also provided. These are disaggregated into the major components of population change consisting of births, deaths, and net migration, and are given subsequent to each population projection total. Additional displays of population pyramids which show distributions of each five year age group as a percentage of the total of each particular group by sex, and white and non-white distinction have also been included, along with the input needed to generated the state totals.

This paper was written by Mr. Chester J. Symanski, Principal Research Technician. Computer programming was performed by Mr. James A. Andrade, Computer Programmer. The report was typed by Mrs. Shirley J. Card.

## PART ONE: INTRODUCTION

The population totals shown in this report reflect the first revisions made of projections originally done by the program using the 1970 census as a base.<sup>1</sup> The most significant factor contributing to the differences between the initial and updated series of figures is that the totals shown in the current report take into consideration the recent temporary drop in birth rates below replacement level prior to 1975, with a gradual return to this level by the year 2000. The earlier report on the other hand was based upon the assumption that the base period rates in 1970 would gradually reach this level by the year 2000. This gap between the two series of birth projections therefore accounts for the major differences between the two series of population forecasts. The revised birth projection input is based upon survey data of birth expectations obtained from the Current Population Survey made by the Bureau of the Census.<sup>2</sup> Since it was found that estimates of recent annual state fluctuations of the total state fertility rate closely paralleled those of the nation as a whole,<sup>3</sup> it was determined that base period rates on a state level could reasonably be tied into future national projections in the absence of current survey data obtained on a state level. This was done by tying directly into ultimate calendar or period rates, rather than forecasting state cohort rates which eventually must be converted back to calendar rates.

Other factors also caused differences between the original and revised totals, but did so to a less significant degree. One of the elements contributing to this change was the use of updated survival rates employing 1969-71 State Life Tables,<sup>4</sup> rather than the 1959-61 ratios originally used, which were the latest available at the time that the projections had to be made. The base period rates were adjusted to account for the actual number of deaths that occurred between 1970 and 1975. This discrepancy exists because the life tables cover only a two year period.

Once the base period rates were calculated a forecast of rates was made by using the same proportional changes expected to occur on a national level.<sup>5</sup>

Differences in the population projection series are also due to changes in the migration assumptions used, since the revised totals take into consideration the reversal in migration trends since 1975, by using a zero net migration rate throughout the period, rather than continuing the slight in-migration of the non-military population which occurred prior to this period.

Each of the assumptions regarding the components of population change were used as input into a cohort-component computer program
